Spring with Spring boot

- Spring framework, Configuration, 3 tier architecture
- What, Why spring boot? Intro to Microservice
- Spring boot CRUD application, with JPA
- Handling Exceptions
- Handling with status code: Using ResponseEntity & http status code
- JSR 303 validation
- hateoas

SOA vs Microservice

Dist computing

rmi, ejb: java sol : both parites should use java

data formate

Spring boot step by step

- Swagger Documentation
- Implementation Filtering for Rest service response
- Versioning RESTful Services
 - Enable cacheing
- Enable ScheduledProcess
- pageable rest response
- Spring mvc jsp
- Spring MVC with thymeleaf
 - Case study: Blog and Comment : one to many Spring boot hibernate
 - Bank application

- Spring framework, Configuration, 3 tier architecture

Spring framework

- Introduction Spring framework, where it fits, design patterns
- Dependency Injection, Configuration-XML, Java
- Aspect Oriented Programming, how it helps, configuration, examples

What is spring framework?

Spring framework is a container that manages life cycle of beans.

It Does 2 primary Jobs:

1. bean wiring
2. bean weaving

A bean is an object that is instantiated, assembled, and managed by a Spring IoC container.

Why Spring framework? Where it fits?

Spring Framework is focused on simplifying enterprise Java development through

- dependency injection
- aspect-oriented programming
- boiler-plate code reduction using template design pattern

JDBC & DAO

Spring Dao
Support &
Spring jdbc
abstraction
framework

ORM

Spring
template
implementation
for
hibernate,
jpa,toplink etc

JEE

Spring Remoting
JMX
JMS
Email
EJB
RMI
WS
Hessian burlap

Web

Spring MVC
Support for various
frameworks
rich view support

AOP module

Spring AOP and AspectJ
integration

Spring Core Contrainer
The IOC Container

Spring framework design patterns

Design Patterns used in Spring Framework

Proxy Design Pattern

Singleton Design Pattern

Factory design pattern

Template Design Pattern

Model View Controller Pattern

Front Controller Pattern

View Helper Pattern

Dependency injection or inversion of control

Service Locator Pattern

Observer-Observable

Context Object Pattern

Java EE vs Spring framework

Spring, Hibernate 3 Tier architecture

Application example: Fund transfer Bank Application

```
public class Account {  
    private int id;  
    private String name;  
    private double balance;  
  
public interface AccountDao {  
    public void update(Account account);  
    public Account find(int id);  
}  
  
public class AccountDaoImp implements AccountDao {  
  
    private Map<Integer, Account> accounts = new HashMap<Integer, Account>();  
  
    public void update(Account account) {  
  
public interface AccountService {  
    public void transfer(int from, int to, int amount);  
    public void deposit(int id, double amount);  
    public Account getAccount(int id);  
}
```

Spring framework

- Introduction Spring framework, where it fits, Spring boot design patterns
- Dependency Injection, Configuration-XML, Java
- Aspect Oriented Programming, how it helps, configuration, examples
- Spring Hibernate

Dependency Injection xml, java configuration

XML Configuration

```
<bean id="accountService" class="com.sample.bank.model.service.AccountServiceImp" autowire="byType"/>
<bean id="accountDao1" class="com.sample.bank.model.persistance.AccountDaoImp"/>
<bean id="accountDao2" class="com.sample.bank.model.persistance.AccountDaoImp" autowire-candidate="false"/>
```

Java Configuration

```
@Configuration
@ComponentScan(basePackages={"com.sample.bank.*"})
@Scope(value="prototype")
public class AppConfig {

    @Bean(autowire=Autowire.BY_TYPE)
    @Scope(value="prototype")
    public AccountService accountService() {
        AccountServiceImp accountService=new AccountServiceImp();
        //accountService.setAccountDao(accountDao());
        return accountService;
    }

    @Bean
    public AccountDao accountDao() {
        AccountDao accountDao=new AccountDaoImp();
        return accountDao;
    }
}
```

```
AnnotationConfigApplicationContext ctx=new AnnotationConfigApplicationContext(AppConfig.class);

AccountService s=ctx.getBean("accountService", AccountService.class);
s.transfer(1, 2, 100);
```

Spring framework

- Introduction Spring framework, where it fits, Spring boot design patterns
- Dependency Injection, Configuration-XML,
- Java

Aspect Oriented Programming, how it helps, configuration, examples

Introduction to AOP

- What is AOP?
 - AOP is a style of programming, mainly good in separating cross cutting concerns
- How AOP works?
 - Achieved usages Proxy design Pattern to separate CCC's form actual code
 - Cross Cutting Concern ?
 - Extra code mixed with the actual code is called CCC's
 - Extra code mixed with code lead to maintenance issues
 - Logging
 - validations
 - Auditing
 - Security

Normal Java Class

```
class Account {  
    public void withdraw() {  
        // Withdraw Logic  
        // Authentication  
        // Logging  
        // Transaction  
    }  
  
    public void deposit() {  
        // Deposit Logic  
        // Authentication  
        // Logging  
        // Transaction  
    }  
}
```

Spring AOP

```
class Account {  
    public void withdraw() {  
        // Withdraw Logic  
    }  
  
    public void deposit() {  
        // deposit Logic  
    }  
}
```

Authentication
Logging
Transaction

AOP - Definitions

- **Advice** defines what needs to be applied and when.
- **Jointpoint** is where the advice is applied.
- **Pointcut** is the combination of different joinpoints where the advice needs to be applied.
- **Aspect** is applying the Advice at the pointcuts.

What, Why spring boot? Intro to Microservice

Service oriented arch SOA

web service soap based ws are popular

Microservice : we dont need enterprise service bus
in order to mange the app
it transfer, convert data from one fromate to another
we can configure ws to intercat with other service
ws mgt, sec...

*big team size
* tech adaption is slow
u cant use diff tech for diff module as they are bunchedled
as singe war file

*scale

The difference between them (from real-life production project) is that SOA project has ESB (like Mule ESB, Camel or other) which intended to route messages (SOAP, JSON etc) from one service to another, and acts like a mediation layer between services.

Services in turn, does not know about each other and just send\receive messages from ESB.

In opposite to SOA, microservice architecture implies that services will communicate with each other directly, using some protocol (usually HTTP). Microservices similar to SOA in that we focus on business functionality and separate it into single, small deployable chunk.

Spring vs Spring Boot

What is Spring Boot?

How Spring boot works?

- Spring use autoconfiguration of bean from spring.factories file

- META-INF/spring.factories

1. Enable
2. Disable

Based on @Conditional and @Configuration

Spring bean auto configuration

Out-of-the-box conditions

Condition	Description
OnBeanCondition	Checks if a bean is in the Spring factory
OnClassCondition	Checks if a class is on the classpath
OnExpressionCondition	Evaluates a SPeL expression
OnJavaCondition	Checks the version of Java
OnJndiCondition	Checks if a JNDI branch exists
OnPropertyCondition	Checks if a property exists
OnResourceCondition	Checks if a resource exists
OnWebApplicationCondition	Checks if a WebApplicationContext exists

Understanding @SpringBootApplication annotation

@SpringBootApplication

Spring Boot

@SpringBootApplication

=

Traditional spring

@Configuration

+

@EnableAutoConfiguration

+

@ComponentScan

Why we need main method in SpringBoot

- Main method is not required for the typical deployment scenario of building a war and placing it in webapps folder of t
- However, if you want to be able to launch the application from within an IDE (e.g. with Eclipse's Run As -> Java Application) while developing or build an executable jar or a war that can run standalone with Spring Boot's embedded tomcat by just java -jar myapp.war command

SpringApplication.run(...);

Following is the high level flow of how spring boot works.

From the run method, the main application context is kicked off which in turn searches for the classes annotated with @configuration, initializes all the declared beans in those configuration classes, and stores those beans in JVM, specifically in a space inside JVM which is known as IOC container. After creation of all the beans, automatically configures the dispatcher servlet and registers the default handler mappings, messageconverts and all other basic things.

run(...) Internal Flow

- Create application context
- Check Application Type
- Register the annotated class beans with the context
- Creates an instance of TomcatEmbeddedServletContainer and adds the context

Using automatic configuration

In a nutshell, Spring Boot auto-configuration is a runtime (more accurately, application startup-time) process that considers several factors to decide what Spring configuration should and should not be applied. To illustrate, here are a few examples of the kinds of things that Spring Boot auto-configuration might consider:

- Is Spring's `JdbcTemplate` available on the classpath? If so and if there is a `Data-Source` bean, then auto-configure a `JdbcTemplate` bean.
- Is Thymeleaf on the classpath? If so, then configure a Thymeleaf template resolver, view resolver, and template engine.
- Is Spring Security on the classpath? If so, then configure a very basic web security setup.

There are nearly 200 such decisions that Spring Boot makes with regard to auto-configuration every time an application starts up, covering such areas as security, integration, persistence, and web development. All of this auto-configuration serves to keep you from having to explicitly write configuration unless absolutely necessary.

```
$ java -jar readinglist-0.0.1-SNAPSHOT.jar --server.port=8000
```

Spring Boot & microservice

Why spring boot?

- What is Spring Boot?
 - Spring Boot is a Framework from “The Spring Team” to ease the bootstrapping and development of new Spring Applications.
 - It provides defaults for code and annotation configuration to quick start new Spring projects within no time.
 - It follows “Opinionated Defaults Configuration” Approach to avoid lot of boilerplate code and configuration to improve Development, Unit Test and Integration Test Process.
- What is NOT Spring Boot?
 - Spring Boot Framework is not implemented from the scratch by The Spring Team, rather than implemented on top of existing Spring Framework (Spring IO Platform).
 - It is not used for solving any new problems

Why spring boot?

- Why Spring Boot?
 - To ease the Java-based applications Development, Unit Test and Integration Test Process.
 - To reduce Development, Unit Test and Integration Test time by providing some defaults.
 - To increase Productivity.

Why spring boot?

- It is very easy to develop Spring Based applications with Java or Groovy.
- It reduces lots of development time and increases productivity.
- It avoids writing lots of boilerplate Code, Annotations and XML Configuration.
- It is very easy to integrate Spring Boot Application with its Spring Ecosystem like Spring JDBC, Spring ORM, Spring Data, Spring Security etc.
- It follows “Opinionated Defaults Configuration” Approach to reduce Developer effort
- It provides Embedded HTTP servers like Tomcat, Jetty etc. to develop and test our web applications very easily.
- It provides CLI (Command Line Interface) tool to develop and test Spring Boot(Java or Groovy) Applications from command prompt very easily and quickly.
- It provides lots of plugins to develop and test Spring Boot Applications very easily using Build Tools like Maven and Gradle
- It provides lots of plugins to work with embedded and in-memory Databases very easily.

Why Spring Boot?-Too much configuration

```
@Configuration
@ComponentScan(basePackages={"com.bookapp"})
@EnableAspectJAutoProxy
@PropertySource(value="db.properties")
@EnableTransactionManagement
public class ModelConfig {

    @Autowired
    private Environment environment;

    @Bean(name="dataSource")
    public DataSource getDataSource(){
        DriverManagerDataSource ds=new DriverManagerDataSource();
        ds.setDriverClassName(environment.getProperty("driver"));
        ds.setUrl(environment.getProperty("url"));
        ds.setUsername(environment.getProperty("username"));
        ds.setPassword(environment.getProperty("password"));
        return ds;
    }

    @Bean
    public LocalSessionFactoryBean getSessionFactory(){
        LocalSessionFactoryBean sf=new LocalSessionFactoryBean();
        sf.setDataSource(getDataSource());
        sf.setPackagesToScan("com.bookapp.model.persistance");
        sf.setHibernateProperties(getHibernateProperties());
        return sf;
    }

    public Properties getHibernateProperties() {
        Properties properties=new Properties();
        properties.setProperty("hibernate.hbm2ddl.auto", "validate");
        properties.setProperty("hibernate.dialect", "org.hibernate.dialect.MySQLDialect");
        properties.setProperty("hibernate.show_sql", "true");
        properties.setProperty("hibernate.format_sql", "true");
        return properties;
    }

    @Bean
    public PersistenceExceptionTranslationPostProcessor
    getPersistenceExceptionTranslationPostProcessor(){
        PersistenceExceptionTranslationPostProcessor ps=
            new PersistenceExceptionTranslationPostProcessor();
        return ps;
    }

    @Bean(name="transactionManager")
    //@@Autowired
    public HibernateTransactionManager getHibernateTransactionManager(SessionFactory factory){
        HibernateTransactionManager tm=new HibernateTransactionManager();
        tm.setSessionFactory(factory);
        return tm;
    }
}
```

Hello World spring boot

```
@RestController  
@SpringBootApplication  
public class RestApplication {  
  
    public static void main(String[] args) {  
        SpringApplication.run(RestApplication.class, args);  
    }  
  
    public String hello(){  
        return "hello to spring boot";  
    }  
}
```

```
1 server.servlet-path=/bookapp  
2 server.port=8080
```

Some fundamentals

What is a Client?

A client is

- Computer
- Mobile
- Host

That sends that **Request** to server for any service, data using HTTP Protocol(using URL) and receive a Response.

What is a Server?

A Server is Remote Machine

That receive request from client and Serve them with appropriate information as **Response** using HTTP/s.

What Happens when we type Google.com

- You enter a URL e.g google.com, Client is browser, request goes to the DNS.
- DNS lookup happens and IP address searched and if found sends back to Browser.
- Now Browser then sends over an HTTP/HTTPS request to the web server's IP.
- The server responds with Resource Page.(index.htm).
- Now Browser will Render the HTML page.

A screenshot of a web browser displaying the MX Toolbox website at mxtoolbox.com/SuperTool.aspx?action=a%3agoogle.com&run=toolpage. The page has a header with the MX TOOLBOX logo and a navigation menu with links like SuperTool, MX Lookup, Blacklists, DMARC, Diagnostics, Domain Health, and DNS Lookups. Below the menu, there is a search bar labeled "SuperTool Beta7" containing the text "google.com". To the right of the search bar is a "DNS Lookup" button. At the bottom of the search results, there is a green button labeled "Find Problems".

What happens when you type a URL in the browser and press enter?

What is Web Service?

They provide a common platform that allows multiple applications built on various programming languages to have the ability to communicate with each other

Service Oriented Architecture

What is REST?

Rest API Basics

Our Clients, send HTTP Requests and wait for responses

Rest API

Receives HTTP requests from Clients and does whatever request needs. i.e create users

Typical HTTP Verbs:

GET -> Read from Database

PUT -> Update/Replace row in Database

PATCH -> Update/Modify row in Database

POST -> Create a new record in the database

DELETE -> Delete from the database

Our Rest API queries the database for what it needs

Response: When the Rest API has what it needs, it sends back a response to the clients. This would typically be in JSON or XML format.

REST characteristics

- ▶ **Resources**: Application state and functionality are abstracted into resources.
 - **URI**: Every resource is uniquely addressable using URIs.
 - **Uniform Interface**: All resources share a uniform interface for the transfer of state between client and resource, consisting of
 - Methods: Use only HTTP methods such as GET, PUT, POST, DELETE, HEAD
 - Representation
- ▶ **Protocol** (The constraints and the principles)
 - **Client-Server**
 - **Stateless**
 - **Cacheable**
 - **Layered**

What is Authentication?

Authentication is a process of presenting your credentials like username, password or another secret key to the system and the system to validate your credentials or you.

	Authentication	Authorization
Meaning	"Are you allowed to access X app?"	"What are you allowed to <i>modify</i> in X app?"
Methods	Password, 2FA, MFA, X509 Certificates, Biometric authenticators, WebAuthN	Access control for URI, Access control lists etc.

In the API terms;

Authentication is used to protect the content over web mean only a valid user with valid credentials can access that API endpoint. These credentials tell the system about who you are. Which enables the system to ensure and confirms a user's identity.

Here system can be anything, it can be a computer, phone, bank or any physical office premises.

Authentication Types

Basic authentication - String is encoded with Base64.

```
curl --header "Authorization: Basic am9objpzZWNyZXQ@"
my-website.com
```

Digest Authentication - Authentication is performed by transmitting the password in an ENCRYPTED form.(With Some Salt etc)

OAuth- Authentication protocol that allows you to approve one application interacting with another on your behalf without giving away your password.

Cookies

Cookies are usually small text files, given ID tags that are stored on your computer's browser directory or program data subfolders.

GET /spec.html HTTP/1.1

Host: www.example.org

Cookie: theme=light; sessionToken=abc123

Record the user's browsing activity.

Which pages were visited in the past.

The screenshot shows a Google Chrome browser window. The address bar displays the URL: chrome.google.com/webstore/detail/editthiscookie/fngmhnnplihplaeedifhccceomcigfbg?hl=en. The top navigation bar shows various browser tabs and icons. A yellow banner at the top right states: "This item has been disabled in Chrome. Enable this item". Below the banner, the page title is "chrome web store". The main content area shows the "EditThisCookie" extension page, which includes a logo of a cookie, the name "EditThisCookie", and the text "Offered by: editthiscookie.com". The page also features a large blue button labeled "Install".

JSON Basics

JSON: JavaScript Object Notation.

When exchanging data between a browser and a server,
the data can only be text.

JSON Data Types.

- JSON Strings : { "name":"John" }
- JSON Numbers : { "age":30 }
- JSON Objects : {

```
"employee":{ "name":"John", "age":30, "city":"New York" }  
}
```

- JSON Arrays
{"employees":["John", "Anna", "Peter"] }
- JSON Booleans
{ "sale":true }
- JSON null
{ "middlename":null }

HyperText Transfer Protocol(HTTP)

- HTTP (Hypertext Transfer Protocol) is perhaps the most popular application protocol used in the Internet (or The WEB).
- An HTTP client sends a request message to an HTTP server. The server, in turn, returns a response message. In other words, HTTP is a pull protocol, the client pulls information from the server (instead of server pushes information down to the client).
- HTTP is a stateless protocol. In other words, the current request does not know what has been done in the previous requests.
- HTTP permits negotiating of data type and representation, so as to allow systems to be built independently of the data being transferred.

HTTP methods & status code

Method	Description
GET	Request to read a Web page
HEAD	Request to read a Web page's header
PUT	Request to store a Web page
POST	Append to a named resource (e.g., a Web page)
DELETE	Remove the Web page
TRACE	Echo the incoming request
CONNECT	Reserved for future use
OPTIONS	Query certain options

- 1xx: Informational Messages
- 2xx: Successful
- 3xx: Redirection
- 4xx: Client Error
- 5xx: Server Error

HTTP Status Codes

For great REST services the correct usage of the correct HTTP status code in a response is vital.

1xx – Informational	2xx – Successful	3xx – Redirection	4xx – Client Error	5xx – Server Error
This class of status code indicates a provisional response, consisting only of the Status-Line and optional headers, and is terminated by an empty line 100 – Continue 101 – Switching Protocols 102 – Processing	This class of status code indicates that the client's request was successfully received, understood, and accepted. 200 – OK 201 – Created 202 – Accepted 203 – Non-Authoritative Information 204 – No Content 205 – Reset Content 206 – Partial Content 207 – Multi-Status	This class of status code indicates that further action needs to be taken by the user agent in order to fulfill the request. 300 – Multiple Choices 301 – Moved Permanently 302 – Found 303 – See Other 304 – Not Modified 305 – Use Proxy 307 – Temporary Redirect	The 4xx class of status code is intended for cases in which the client seems to have erred.	Response status codes beginning with the digit "5" indicate cases in which the server is aware that it has erred or is incapable of performing the request. 500 – Internal Server Error 501 – Not Implemented 502 – Bad Gateway 503 – Service Unavailable 504 – Gateway Timeout 505 – HTTP Version Not Supported 506 – Variant Also Negotiates 507 – Insufficient Storage 510 – Not Extended

Examples of using HTTP Status Codes in REST

201 – When doing a POST to create a new resource it is best to return 201 and not 200.
204 – When deleting a resources it is best to return 204, which indicates it succeeded but there is no body to return.
301 – If a 301 is returned the client should update any cached URI's to point to the new URI.
302 – This is often used for temporary redirect's, however 303 and 307 are better choices.
409 – This provides a great way to deal with conflicts caused by multiple updates.
501 – This implies that the feature will be implemented in the future.

Special Cases

306 – This status code is no longer used. It used to be for switch proxy.
418 – This status code from RFC 2324. However RFC 2324 was submitted as an April Fools' Joke. The message is *I am a teapot.*

400 – Bad Request
401 – Unauthorised
402 – Payment Required
403 – Forbidden
404 – Not Found
405 – Method Not Allowed
406 – Not Acceptable
407 – Proxy Authentication Required
408 – Request Timeout
409 – Conflict
410 – Gone
411 – Length Required
412 – Precondition Failed
413 – Request Entity Too Large
414 – Request URI Too Long
415 – Unsupported Media Type
416 – Requested Range Not Satisfiable
417 – Expectation Failed
422 – Unprocessable Entity
423 – Locked
424 – Failed Dependency
425 – Unordered Collection
426 – Upgrade Required

Key	Description
Black	HTTP version 1.0
Blue	HTTP version 1.1
Aqua	Extension RFC 2295
Green	Extension RFC 2518
Yellow	Extension RFC 2774
Orange	Extension RFC 2817
Purple	Extension RFC 3648
Red	Extension RFC 4918

Difference between GET and POST Http methods:

	GET	POST
1	It is used for getting information from the server side	It is used to post the information to the server.
2	It performs read-only operation	It performs update/write operation.
3	Whatever the request can be sent that is append with URL	Whatever request send to the server that is not exposed in the URL
4	Only text or character type of data can be sent	Any type of data can be send
5	Limited amount of data can be send (up to 2KB)	No length limit of data that we can send
6	It provides less security because the user's request is directly exposed in URL bar. Hence, sensitive information is not recommended to be send.	It provides high security
7	Bookmarking is possible which is the advantage	Bookmarking is not possible
8	Caching is also possible which is also another advantage of get method	Caching is not possible

Generally – **not** necessarily – **POST** APIs are used to create a new resource on server. So when you invoke the same **POST** request N times, you will have N new resources on the server. So, **POST** is not idempotent.

PUT	POST
<p>Replacing existing resource or Creating if resource is not exist</p> <p><i>http://www.example.com/customer/{id}</i> <i>http://www.example.com/customer/123/orders/456</i></p> <p>Identifier is chosen by the client</p>	<p>Creating new resources (and subordinate resources)</p> <p><i>http://www.example.com/customer/</i> <i>http://www.example.com/customer/123/orders</i></p> <p>Identifier is returned by server</p>
<p>Idempotent i.e. if you PUT a resource twice, it has no effect.</p> <p>Ex: Do it as many times as you want, the result will be same. <code>x=1;</code></p>	<p>POST is neither safe nor idempotent. It is therefore recommended for non-idempotent resource requests.</p> <p>Ex: <code>x++;</code></p>
Works as specific	Works as abstractive
If you create or update a resource using PUT and then make that same call again, the resource is still there and still has the same state as it did with the first call.	Making two identical POST requests will most-likely result in two resources containing the same information.

spring boot hello world, CRUD
application

@SpringBootApplication

User configuration

`@ComponentScan`

Auto configuration

`@EnableAutoConfiguration`

<code>@Repository</code>	<code>@Configuration</code>
<code>@Component</code>	
<code>@Controller</code>	<code>@Service</code>
<code>@RestController</code>	

Spring boot hello world

```
@RestController
@RequestMapping(path = "api")
public class Hello {

    private Logger logger = LoggerFactory.getLogger(Hello.class);

    @GetMapping(path = "hello/{name}/{address}")
    public String helloWithName(@PathVariable(name = "name") String name,
                                @PathVariable(name = "address") String address) {
        return "hello spring rest:" + name + ":" + address;
    }

    @GetMapping(path = "hello")
    public String helloWithRequestParam(
            @RequestParam(name = "name", required = false, defaultValue = "amit") String name,
            @RequestParam(name = "age", required = false, defaultValue = "30") int age) {
        logger.info("spring boot hello world.....");
        return "hello spring rest:" + name + ":" + age;
    }
}
```

Creating DAO, DTO

```
@Entity  
@Table(name="book_table")  
public class Book {  
    @Id @GeneratedValue(strategy=GenerationType.IDENTITY)  
    private Integer id;  
    private String title;  
    private String author;  
    private double price;  
    private String pubName;  
    @Temporal(TemporalType.DATE)  
    private Date pubDate;
```

```
@Repository  
public interface BookRepo extends CrudRepository<Book, Integer> {  
    public List<Book>findByTitle(String title);  
}
```

Hibernate/JPA integration

- Step 1: configure hibernate in

```
1 spring.datasource.url=jdbc:mysql://localhost:3306/boot_demo?useSSL=false
2 spring.datasource.username=root
3 spring.datasource.password=root
4 spring.datasource.driver-class-name=com.mysql.cj.jdbc.Driver
5
6
7
8
9 spring.jpa.hibernate.ddl-auto=update
0 logging.level.org.springframework.web: DEBUG
1 logging.level.org.hibernate: ERROR
2 spring.jpa.show-sql=true
```

- Step 2: Annotate
POJO

```
@Entity
@Table(name="book_table")
public class Book {
    @Id @GeneratedValue(strategy=GenerationType.IDENTITY)
    private int id;
    @Column(nullable=false, unique=true, name="isbn")
    private String isbn;
```

-

- Step 3: Just inject
EntityManager

```
@Repository
public class BookDaoImplHib implements BookDao{
    @Autowired
    private EntityManager em;
    @Override
    public List<Book> getAllBooks() {
        return em.createQuery("from Book", Book.class).getResultList();
    }
}
```

Spring boot bootstrapping

```
@SpringBootApplication
@ComponentScan({"com.bookapp"})
@EntityScan("com.bookapp.model.dao")
@EnableJpaRepositories("com.bookapp.model.dao")
public class BookappspringbootApplication {

    public static void main(String[] args) {
        SpringApplication.run(BookappspringbootApplication.class, args);
    }

}
```

- <https://stackoverflow.com/questions/40384056/consider-defining-a-bean-of-type-package-in-your-configuration-spring-boot>

Spring Data

```
public interface CrudRepository<T, ID extends Serializable>
    extends Repository<T, ID> {
    <S extends T> S save(S entity);
    T findOne(ID primaryKey);
    Iterable<T> findAll();
    Long count();
    void delete(T entity);
    boolean exists(ID primaryKey);
    // ... more functionality omitted.
}
```

Query Lookup Strategy

Keyword	Sample	JPQL snippet
And	findByLastnameAndFirstname	... where x.lastname = ?1 and x.firstname = ?2
Or	findByLastnameOrFirstname	... where x.lastname = ?1 or x.firstname = ?2
Between	findByStartDateBetween	... where x.startDate between ?1 and ?2
LessThan	findByAgeLessThan	... where x.age < ?1
GreaterThan	findByAgeGreaterThan	... where x.age > ?1
After	findByStartDateAfter	... where x.startDate > ?1
Before	findByStartDateBefore	... where x.startDate < ?1
IsNull	findByAgeIsNull	... where x.age is null
IsNotNull,NotNull	findByAge(Is)NotNull	... where x.age not null
Like	findByFirstnameLike	... where x.firstname like ?1
NotLike	findByFirstnameNotLike	... where x.firstname not like ?1
StartingWith	findByFirstnameStartingWith	... where x.firstname like ?1 (parameter bound with prepended %)
ngWith	findByFirstnameEndingWith	... where x.firstname like ?1 (parameter bound with appended %)
Containing	findByFirstnameContaining	... where x.firstname like ?1 (parameter bound wrapped in %)
OrderBy	findByAgeOrderByLastnameDesc	... where x.age = ?1 order by x.lastname desc
Not	findByLastnameNot	... where x.lastname <> ?1
In	findByAgeIn(Collection<Age> ages)	... where x.age in ?1
NotIn	findByAgeNotIn(Collection<Age> age)	... where x.age not in ?1
True	findByActiveTrue()	... where x.active = true
False	findByActiveFalse()	... where x.active = false

Query Lookup Strategy

- @NamedQuery

```
@Entity
@NamedQuery(name = "User.findByEmailAddress",
    query = "select u from User u where u.emailAddress = ?1")
public class User {

}

public interface UserRepository extends JpaRepository<User, Long> {

    List<User> findByLastname(String lastname);

    User findByEmailAddress(String emailAddress);
}
```

@Query

```
public interface UserRepository extends JpaRepository<User, Long> {

    @Query("select u from User u where u.emailAddress = ?1")
    User findByEmailAddress(String emailAddress);
}
```

Spring boot implement service layer

Step 4: Service layer

```
public interface BookService {  
  
    public List<Book> getAllBooks();  
    public Book getBookById(int id);  
    public Book addBook(Book book);  
    public List<Book> getBookByTitle(String title);  
    public Book updateBook(int bookId, Book book);  
    public Book deleteBook(int bookId);  
  
}  
  
@ResponseStatus(code=HttpStatus.NOT_FOUND)  
public class BookNotFoundException extends RuntimeException{  
    private static final long serialVersionUID = 4351688402749113855L;  
}
```

Service layer implementation

```
@Service
@Transactional
public class BookServiceImpl implements BookService{
    @Autowired
    private BookRepo bookRepo;

    @Override
    public List<Book> getAllBooks() {
        return (List<Book>) bookRepo.findAll();
    }

    @Override
    public Book getBookById(int id) {
        return bookRepo.findById(id).orElseThrow(BookNotFoundException::new);
    }

    @Override
    public Book addBook(Book book) {
        return bookRepo.save(book);
    }

    @Override
    public List<Book> getBookByTitle(String title) {
        return bookRepo.findByTitle(title);
    }

    @Override
    public Book updateBook(int bookId, Book book) {
```

Service layer implementation

```
@Override  
public Book addBook(Book book) {  
    return bookRepo.save(book);  
}  
  
@Override  
public List<Book> getBookByTitle(String title) {  
    return bookRepo.findByTitle(title);  
}  
  
@Override  
public Book updateBook(int bookId, Book book) {  
    Book bookToUpdate=getBookById(bookId);  
    bookToUpdate.setPrice(book.getPrice());  
  
    return bookRepo.save(bookToUpdate);  
}  
|  
@Override  
public Book deleteBook(int bookId) {  
    Book bookToDelete=getBookById(bookId);  
    bookRepo.delete(bookToDelete);  
    return bookToDelete;  
}
```

Rest Controller

Step 5: Rest controller

```
@RestController  
 @RequestMapping(path="api")  
 public class BookRestController {  
  
     @Autowired  
     private BookService bookService;  
  
     @GetMapping(path="book", produces=MediaType.APPLICATION_JSON_VALUE)  
     public List<Book> getAllBooks(){  
         return bookService.getAllBooks();  
     }  
  
     @GetMapping(path="book/{id}", produces=MediaType.APPLICATION_JSON_VALUE)  
     public Book getBookById(@PathVariable(name="id")int id){  
         return bookService.getBookById(id);  
     }  
  
     @PostMapping(path="book", produces=MediaType.APPLICATION_JSON_VALUE  
                 ,consumes=MediaType.APPLICATION_JSON_VALUE)  
     public Book addBook(@RequestBody Book book){  
         return bookService.addBook(book);  
     }  
  
     @PutMapping(path="book/{id}", produces=MediaType.APPLICATION_JSON_VALUE  
                 ,consumes=MediaType.APPLICATION_JSON_VALUE)  
     public Book updateBook(@PathVariable(name="id")int id, @RequestBody Book book){  
         return bookService.updateBook(id, book);  
     }  
}
```

Rest controller

```
@PutMapping(path="book/{id}", produces=MediaType.APPLICATION_JSON_VALUE  
        ,consumes=MediaType.APPLICATION_JSON_VALUE)  
public Book updateBook(@PathVariable(name="id")int id, @RequestBody Book book){  
    return bookService.updateBook(id, book);  
}  
  
@DeleteMapping(path="book/{id}", produces=MediaType.APPLICATION_JSON_VALUE)  
public Book deleteBook(@PathVariable(name="id")int id){  
    return bookService.deleteBook(id);  
}
```

Step 6: Spring boot config

```
server.servlet.context-path=/bookapp
server.port=8080

spring.datasource.url=jdbc:mysql://localhost:3306/hcl_jdbc?useSSL=false
spring.datasource.username=root
spring.datasource.password=root
spring.datasource.driver-class-name=com.mysql.cj.jdbc.Driver

spring.jpa.hibernate.ddl-auto=update
logging.level.org.springframework.web: DEBUG
logging.level.org.hibernate: ERROR
spring.jpa.show-sql=true

@SpringBootApplication
public class BookappApplication implements CommandLineRunner{

    @Autowired
    private BookService bookService;

    public static void main(String[] args) {
        SpringApplication.run(BookappApplication.class, args);
    }

    @Override
    public void run(String... args) throws Exception {
        bookService.addBook(new Book("head first java", "katthy", 560, "abc", new Date()));
        bookService.addBook(new Book("head first design pattern", "katthy", 760, "abc", new Date()));
    }
}
```

Spring boot profile

The screenshot shows the Eclipse IDE interface with the following details:

- Project Explorer:** Shows the project structure for "spring-profile [boot] [devtools]". It includes the following packages:
 - src/main/java:
 - com.javatechie.spring.profile.api:
 - SpringProfileApplication.java
 - com.javatechie.spring.profile.api.controller:
 - UserController.java
 - com.javatechie.spring.profile.api.dao:
 - UserRepository.java
 - com.javatechie.spring.profile.api.model
 - com.javatechie.spring.profile.api.service:
 - UserService.java
 - src/main/resources:
 - static
 - templates
 - application-dev.properties
 - application-prod.properties
 - application.properties
- Code Editor:** Displays the content of the application.properties file:

```
1 spring.datasource.driver-class-name=com.mysql.jdbc.Driver
2 spring.datasource.url = jdbc:mysql://localhost:3306/local
3 spring.datasource.username = root
4 spring.datasource.password = cisco
5 spring.jpa.show-sql = true
6 spring.jpa.hibernate.ddl-auto = update
7 spring.jpa.properties.hibernate.dialect = org.hibernate.dialect.MySQL5Dialect
8 #SET PROFILE TO SWITCH ENVIRONMENT TO ENVIRONMENT
9 spring.profiles.active=local
```
- Console:** Shows the application logs:

```
SpringProfileApplication [Java Application] C:\Program Files\Java\jre1.8.0_162\bin\javaw.exe (Mar 29, 2018, 3:08:47 PM)
2018-03-29 15:10:25.320  INFO 34196 --- [ restartedMain] org.hibernate.dialect.Dialect      : HHH000400
2018-03-29 15:10:25.363  INFO 34196 --- [ restartedMain] org.hibernate.tool.hbm2ddl.SchemaUpdate : HHH000228
```

Spring REST exception handling

Step 7: Handling BookNotFoundException

```
@ResponseStatus(value=HttpStatus.NOT_FOUND)
public class BookNotFoundException extends RuntimeException {
    private static final long serialVersionUID = -2906350775886465681L;
}

@ControllerAdvice          aop "throws advice"
@RestController
public class ExceptionHandlerController {

    @ExceptionHandler(BookNotFoundException.class)
    public ResponseEntity<Object> handleBookNotFoundEx(BookNotFoundException ex, WebRequest req){
        ErrorDetails details=new ErrorDetails(new Date(), "book not found", req.getDescription(false));
        return new ResponseEntity<Object>(details, HttpStatus.NOT_FOUND);
    }
}

@ExceptionHandler(Exception.class)
public final ResponseEntity<Object> handleAllExceptions(Exception ex,
    WebRequest request) {
    ErrorDetails errorDetails = new ErrorDetails(new Date(),
        ex.getMessage(), request.getDescription(false));
    return new ResponseEntity<Object>(errorDetails, HttpStatus.INTERNAL_SERVER_ERROR);
}

public class ErrorDetails {
    private Date timestamp;
    private String message;
    private String details;
```

REST Handling
HttpStatus code

Step 8: Handling HttpStatus code

- @RestController
- // @RestController=@Controller +
@ResponseBody

HTTP Status Codes

Code	Description	Code	Description
200	OK	400	Bad Request
201	Created	401	Unauthorized
202	Accepted	403	Forbidden
301	Moved Permanently	404	Not Found
303	See Other	410	Gone
304	Not Modified	500	Internal Server Error
307	Temporary Redirect	503	Service Unavailable

REST Using Response Entity and Status
code

Step 8: Using ResponseEntity

```
@RestController
@RequestMapping(path="api")
public class BookRestController {

    @Autowired
    private BookService bookService;

    @GetMapping(path="book", produces=MediaType.APPLICATION_JSON_VALUE)
    public ResponseEntity<List<Book> > getAllBooks(){
        return new ResponseEntity<List<Book>>(bookService.getAllBooks(), HttpStatus.OK);
    }

    @GetMapping(path="book/{id}", produces=MediaType.APPLICATION_JSON_VALUE)
    public ResponseEntity<Book> getBookById(@PathVariable(name="id")int id){
        return new ResponseEntity<Book>(bookService.getBookById(id), HttpStatus.OK);
    }

    @PostMapping(path="book", produces=MediaType.APPLICATION_JSON_VALUE
                 ,consumes=MediaType.APPLICATION_JSON_VALUE)
    public ResponseEntity<Book> addBook(@RequestBody Book book){
        return new ResponseEntity<Book>(bookService.addBook(book), HttpStatus.CREATED);
    }

    @PutMapping(path="book/{id}", produces=MediaType.APPLICATION_JSON_VALUE
                ,consumes=MediaType.APPLICATION_JSON_VALUE)
    public ResponseEntity<Book> updateBook(@PathVariable(name="id")int id, @RequestBody Book book){
        return new ResponseEntity<Book>(bookService.updateBook(id, book), HttpStatus.CREATED);
    }

    @DeleteMapping(path="book/{id}", produces=MediaType.APPLICATION_JSON_VALUE)
    public ResponseEntity<Void> deleteBook(@PathVariable(name="id")int id){
        bookService.deleteBook(id);
        return new ResponseEntity<Void>(HttpStatus.NO_CONTENT);
    }
}
```

JSR 303 validation

Step 9: JSR 303 validation

```
@Entity  
@Table(name="book_table")  
public class Book {  
    @Id @GeneratedValue(strategy=GenerationType.IDENTITY)  
    private Integer id;  
  
    @Size(min=2, message="title should have atleast 4 characters")  
    private String title;  
  
    @PostMapping(path="book", produces=MediaType.APPLICATION_JSON_VALUE  
                 ,consumes=MediaType.APPLICATION_JSON_VALUE)  
    public ResponseEntity<Book> addBook(@Valid @RequestBody Book book){  
        return new ResponseEntity<Book>(bookService.addBook(book), HttpStatus.CREATED);  
    }  
  
    @ControllerAdvice  
    @RestController  
    public class ExceptionHandlerController extends ResponseEntityExceptionHandler{  
        @Override  
        protected ResponseEntity<Object> handleMethodArgumentNotValid(MethodArgumentNotValidException ex,  
                         HttpHeaders headers, HttpStatus status, WebRequest request) {  
            ErrorDetails errorDetails = new ErrorDetails(new Date(), "Validation Failed",  
                  ex.getBindingResult().toString());  
            return new ResponseEntity<Object>(errorDetails, HttpStatus.BAD_REQUEST);  
        }  
    }  
}
```

4

REST:

HATEOAS

Hypermedia as the Engine of Application State

HATEOAS (Hypermedia as the Engine of Application State) is a constraint of the REST application architecture that keeps the RESTful style architecture unique from most other network application architectures.

Step 10: hateoas

Hypermedia as the Engine of Application State (**HATEOAS**) is a component of the REST application architecture that distinguishes it from other network application architectures. With **HATEOAS**, a client interacts with a network application whose application servers provide information dynamically through hypermedia.

```
HTTP/1.1 200 OK
Content-Type: application/vnd.acme.account+json
Content-Length: ...

{
  "account": {
    "account_number": 12345,
    "balance": {
      "currency": "usd",
      "value": 100.00
    },
    "links": {
      "deposit": "/accounts/12345/deposit",
      "withdraw": "/accounts/12345/withdraw",
      "transfer": "/accounts/12345/transfer",
      "close": "/accounts/12345/close"
    }
  }
}
```

Glory of REST

Level 3: Hypermedia Controls

Level 2: HTTP Verbs

Level 1: Resources

Level 0: The Swamp of POX

By including links in returned representations , the server can remove the burden from the user-agent of determining what actions can be taken based on the current application state and knowing who to interact with in order to achieve that goal.

As the server has no knowledge of the user-agent's current state other than what it receives in a request, it is important that the user-agent tries to avoid using state other than the representations returned from the server. This ensures that the available actions provided by the server are based the most complete understanding of the user-agent state as possible.

little code to manage state as its actions shed purely on the received

Hateoas

- HATEOAS- Hypertext as the engine of Application state
- Use link in the application state (Response data)
- **Advantage:**
 - the client can have a single entry point to the application and all the further action can be taken
 - based on the links in the response data
 - Reduce dependency between client and service, so that the server can make changes to its URI without breaking the client side code
- **Implementation:**
 - RepresentationModel
 - WebMvcLinkBuilder
 - Link

Spring REST :HATEOAS Steps

- Step 1: Put Hateoas dependencies
- Step 2: Make POJO extends a class RepresentationModel

```
• @Entity  
• @Table(name = "book_table")  
• public class Book extends RepresentationModel<Book>{  
  
• @GetMapping(path = "/book2/{id}", produces = MediaType.APPLICATION_JSON_VALUE)  
public EntityModel<Book> getBookById2(@PathVariable(name = "id") int id) {  
    Link link=WebMvcLinkBuilder  
        .linkTo(WebMvcLinkBuilder.methodOn(BookRestController.class).getBookById2(id))  
        .withSelfRel();  
  
    Book book = bookService.getBookById(id);  
    book.add(link);  
  
    return EntityModel.of(book);  
}
```

```
{  
  "id": 1,  
  "isbn": "AQ12",  
  "title": "spring in action",  
  "author": "rajeev gupta",  
  "price": 560.0,  
  "date": "2017-04-12",  
  "_links": {  
    "self": {  
      "href": "http://localhost:9000/bookappbook/1"  
    }  
  }  
}
```

Spring REST :HATEOAS Steps

```
// get all the books
@GetMapping(path = "book", produces = MediaType.APPLICATION_JSON_VALUE)
public CollectionModel<Book> getAllBooks() {
    List<Book> books = bookService.getAllBooks();
    for(Book book: books) {
        Link link=WebMvcLinkBuilder
            .linkTo(WebMvcLinkBuilder.methodOn(BookRestController.class).getBookById(book.getId()))
            .withSelfRel();
        book.add(link);
    }
    return CollectionModel.of(books);
}
```

framework for documentation of rest web service

Swagger documentation

Step 11: swagger documentation

► What & Why Swagger :-

► Swagger Eco system :-

- Swagger UI
- Swagger Editor
- Swagger Codegen

► Swagger Specification :-

- Resource Listing - Can be JSON or YAML, Case sensitive fields
- API Description with Details

Step 11: swagger documentation

```
@Configuration  
@EnableSwagger2  
public class SwaggerConfig {  
    public Docket api() {  
        return new Docket(DocumentationType.SWAGGER_2);  
    }  
}
```

Api Documentation

Api Documentation

[Apache 2.0](#)

<http://localhost:8080/swagger-ui.html>

The screenshot shows the official Swagger website. It features a large green circle with three white dots in the center. To the right of the circle is a grid of four screenshots showing the Swagger UI interface. Below the screenshots, the word 'Swagger' is written in a large, bold, black font. Underneath it, the word 'Software' is written in a smaller, gray font. A share icon is located to the right of the software name. The main text area describes Swagger as an open-source software framework backed by a large ecosystem of tools that helps developers design, build, document, and consume RESTful web services. A link to 'Wikipedia' is provided at the end of the text.

Swagger

Software

Swagger is an open-source software framework backed by a large ecosystem of tools that helps developers design, build, document, and consume RESTful web services. [Wikipedia](#)

</dependency>
```

Swagger Doc Customization

```
@Configuration
@EnableSwagger2
public class SwaggerConfig {

    public static final Contact DEFAULT_CONTACT = new Contact("rajeev gupta",
        "http://abc.com", "rgupta.mtech@gmail.com");

    public static final ApiInfo DEFAULT_API_INFO = new ApiInfo(
        "Awesome API Title", "Awesome API Description", "1.0", "urn:tos",
        DEFAULT_CONTACT, "Apache 2.0",
        "http://www.apache.org/licenses/LICENSE-2.0");

    private static final Set<String> DEFAULT_PRODUCES_AND_CONSUMES = new HashSet<String>(
        Arrays.asList("application/json", "application/xml"));

    @Bean
    public Docket api() {
        return new Docket(DocumentationType.SWAGGER_2)
            .apiInfo(DEFAULT_API_INFO)
            .produces(DEFAULT_PRODUCES_AND_CONSUMES)
            .consumes(DEFAULT_PRODUCES_AND_CONSUMES);
    }
}
```

Customization of swagger doc

```
@SwaggerDefinition(  
    info = @Info(  
        description = "Awesome Resources",  
        version = "V12.0.12",  
        title = "Awesome Resource API",  
        contact = @Contact(  
            name = "rajeev gupta",  
            email = "rgupta.mtech@gmail.com",  
            url = "http://abc.com"  
        ),  
        license = @License(  
            name = "Apache 2.0",  
            url = "http://www.apache.org/licenses/LICENSE-2.0"  
        )  
    ),  
    consumes = {"application/json", "application/xml"},  
    produces = {"application/json", "application/xml"},  
    schemes = {SwaggerDefinition.Scheme.HTTP, SwaggerDefinition.Scheme.HTTPS},  
    externalDocs = @ExternalDocs(value = "Read This For Sure", url = "http://abc.com")  
)  
public interface UserApiDocumentationConfig {  
}
```

```
@ApiModel(description="information about book")  
public class Book {  
    private int id;  
    private String isbn;  
    @ApiModelProperty(notes="should be min 4 char and max 30 char")  
    @Size(min=5, max=30, message="title must be between 5 to 30 char")  
    private String title;
```

Implementing Filtering for RESTful Service

Step 12: Implementing Filtering for RESTful Service

- What if dont want to expose some property as rest end point?

```
//@JsonIgnoreProperties(value={"field1","field2"})
public class SomeBean {
    private String field1;

    @JsonIgnore
    private String field2;
    private String field3;
```

```
@RestController
public class FilteringController {
    @RequestMapping("/filterdemo")
    public SomeBean getBean(){
        return new SomeBean("value 1", "value 2", "value 3");
    }

    @RequestMapping("/filterdemo-list")
    public List<SomeBean> getBeanList(){
        List<SomeBean> beans=Arrays.asList(new SomeBean("value 1", "value 2", "value 3"),
            new SomeBean("value 1", "value 2", "value 3"));
        return beans ;
    }
}
```

Implementing Enable cacheing

Step 13: Enable caching

Ehcache is an open source, standards-based cache that boosts performance, offloads your database, and simplifies scalability. It's the most widely-used Java-based cache because it's robust, proven, full-featured, and integrates with other popular libraries and frameworks.

30.3 Declarative annotation-based caching

For caching declaration, the abstraction provides a set of Java annotations:

- `@Cacheable` triggers cache population
- `@CacheEvict` triggers cache eviction
- `@CachePut` updates the cache without interfering with the method execution
- `@Caching` regroups multiple cache operations to be applied on a method
- `@CacheConfig` shares some common cache-related settings at class-level

Step 13: Enable caching

```
import com.nookapp.model.service.BookService;
@EnableCaching
@SpringBootApplication
public class Bookapp2Application implements CommandLineRunner {
    @Autowired
    private BookService bookService;
    @Bean
    public CacheManager cacheManager(){
        ConcurrentMapCacheManager cacheManager=new ConcurrentMapCacheManager("books");
        return cacheManager;
    }
}
```

```
@Service
@Transactional
public class BookServiceImpl implements BookService {
    @Autowired

        bookToBeUpdate.setPrice(book.getPrice());

        return dao.save(bookToBeUpdate);
    }

    @CacheEvict(value="books", allEntries=true)
    public void evictCache() {}
}

```

mycache

22	object

```

@Configuration
@EnableScheduling
@ConditionalOnProperty(name = "scheduling.enabled", matchIfMissing = true)
class SchedulingConfiguration {

```

Implementing Enable Scheduled process

Step 14: Enable Scheduled process

- <https://stackoverflow.com/questions/16407750/how-often-you-do-this-in-a-cron-0>

```
@Component
public class ScheduledJob {
    private Logger logger = LoggerFactory.getLogger(this.getClass());
    @Autowired
    private BookService service;

    @Scheduled(cron = "0,30 * * * *")
    public void cronJob() {
        logger.info("> cronJob");
        // Add scheduled logic here
        Collection<Book> books = service.getAllBooks();
        logger.info("There are {} books in the data store.", books.size());
        logger.info("< cronJob");
    }
    @Scheduled(initialDelay = 5000, fixedRate = 15000)
    public void fixedRateJob() {
        logger.info("> fixedRateJob");
        // Add scheduled logic here

        Collection<Book> greetings = service.getAllBooks();
        logger.info("There are {} books in the data store.", greetings.size());

        logger.info("< fixedRateJob");
    }
}
```

Enable Scheduled process

@Scheduled(cron = "0 15 10 15 * ?", zone = "Europe/Paris")

It will work once every hour, exactly at x:00.

Keep in mind the format of crontab is:

```
+----- minute (0 - 59)
| +----- hour (0 - 23)
| | +----- day of month (1 - 31)
| | | +----- month (1 - 12)
| | | | +---- day of week (0 - 6) (Sunday=0 or 7)
| | | | |
* * * * * command to be executed
```

so 0 in the first position means every minute 0, any hour, and day.

Versioning RESTful Services

Step 15: Versioning RESTful Services - Basic Approach with URIs

- - Versioning?
 - Media type versioning (aka "content negotiation" or " accept header")- Github
 - Custom headers versioning- Microsoft
 - URI versioning -Twitter
 - Parameter versioning -Amazon
- - Factors effect decision
 - url pollution
 - misuse of http headers
 - caching
 - can we execute teh request on browser?
 - api doc
 - No perfect sol

Spring REST versioning example

```
public class Name {  
    private String firstName;  
    private String lastName;
```

```
3 public class PersonV1 {  
4     private String name;  
5 }
```

```
public class PersonV2 {  
    private Name name;
```

```
@RestController  
public class PersonVersioningController {  
    @GetMapping("v1/person")  
    public PersonV1 personV1() {  
        return new PersonV1("rajeev gupta");  
    }  
    @GetMapping("v2/person")  
    public PersonV2 personV2() {  
        return new PersonV2(new Name("rajeev", "gupta"));  
    }  
    @GetMapping(value = "/person/param", params = "version=1")  
    public PersonV1 paramV1() {  
        return new PersonV1("rajeev gupta");  
    }  
    @GetMapping(value = "/person/param", params = "version=2")  
    public PersonV2 paramV2() {  
        return new PersonV2(new Name("rajeev", "gupta"));  
    }  
    @GetMapping(value = "/person/header", headers = "X-API-VERSION=1")  
    public PersonV1 headerV1() {  
        return new PersonV1("rajeev gupta");  
    }  
    @GetMapping(value = "/person/header", headers = "X-API-VERSION=2")  
    public PersonV2 headerV2() {  
        return new PersonV2(new Name("rajeev", "gupta"));  
    }  
    @GetMapping(value = "/person/produces", produces = "application/vnd.company.app-v1+json")  
    public PersonV1 producesV1() {  
        return new PersonV1("rajeev gupta");  
    }  
    @GetMapping(value = "/person/produces", produces = "application/vnd.company.app-v2+json")  
    public PersonV2 producesV2() {  
        return new PersonV2(new Name("rajeev", "gupta"));  
    }  
}
```

Pagable rest response

Step 16: pageable rest response

```
public List<Book> getAllBooksPagable(Pageable pageable);
```

```
@Override  
public List<Book> getAllBooksPagable(Pageable pageable) {  
    return dao.findAll(pageable).getContent();  
}
```

```
@GetMapping(path = "/bookpage", produces = MediaType.APPLICATION_JSON_VALUE)  
public ResponseEntity<List<Book>> getAllBooksPagination(Pageable pageable) {  
    return new ResponseEntity<List<Book>>(  
        bookService.getAllBooksPagable(pageable), HttpStatus.OK);  
}
```

Spring MVC with JSP

Spring MVC

Step 18: spring boot jsp

```
spring.mvc.view.prefix=/WEB-INF/views/  
spring.mvc.view.suffix=.jsp
```

```
@Controller  
public class BookController {  
  
    private BookService bookService;  
  
    @Autowired  
    public BookController(BookService bookService) {  
        this.bookService = bookService;  
    }  
  
    @GetMapping(path="allbooks")  
    public ModelAndView allbooks(ModelAndView mv){  
        mv.addObject("books",bookService.getAllBooks());  
        mv.setViewName("books");  
        return mv;  
    }  
    @GetMapping(path="addbook")  
    public String addBookGet(Model model){  
        model.addAttribute("book", new Book());  
        return "addbook";  
    }  
    @PostMapping(path="addbook")  
    public String addBookPost(Book book){  
        bookService.addBook(book);  
        return "redirect:/allbooks";  
    }  
}
```

```
<dependency>  
    <groupId>org.apache.tomcat.embed</groupId>  
    <artifactId>tomcat-embed-jasper</artifactId>  
</dependency>  
  
<dependency>  
    <groupId>javax.servlet</groupId>  
    <artifactId>jstl</artifactId>  
</dependency>  
  
<dependency>  
    <groupId>javax.xml.bind</groupId>  
    <artifactId>jaxb-api</artifactId>  
</dependency>
```

```
> <table border="1">
>
>     <thead>
>         <tr>
>             <th>id</th>
>             <th>isbn</th>
>             <th>title</th>
>             <th>author</th>
>             <th>price</th>
>             <th>pub email</th>
>             <th>publisher</th>
>             <th>pub date</th>
>         </tr>
>     </thead>
>     <tbody>
>         <c:forEach items="${books}" var="book">
>             <tr>
>                 <td>${book.id }</td>
>                 <td>${book.isbn }</td>
>                 <td>${book.title }</td>
>                 <td>${book.author }</td>
>                 <td>${book.price }</td>
>                 <td>${book.pubEmail }</td>
>                 <td>${book.publisher }</td>
>                 <td><fmt:formatDate value="${book.pubDate }" pattern="dd/MM/yyyy"/></td>
>             </tr>
>         </c:forEach>
>     </tbody>
> </table>
<a href="addbook">addbook</a>
```

Double Posting Scenario

```
@RequestMapping(value = "/createUser", method = RequestMethod.POST)
public String createUserAcc(@ModelAttribute("userModel") User user, RedirectAttributes attribues) {
    logger.info(" user form submitted :: " + user);

    // logic to insert record to DB

    //model.addAttribute("msg", "Account Created Successfully");
    attribues.addFlashAttribute("msg", "Account Created Successfully"); I

    return "redirect:/userAccCreationSuccess";
}

/**
 * This method is used to display sucess msg post registration
 *
 * @return
 */
@RequestMapping(value = "/userAccCreationSuccess", method = RequestMethod.GET)
public String userAccCreationSuccess(Model model) {
    logger.info(" userAccCreationSuccess() method called ");
    model.addAttribute("userModel", new User());
    return "createUserAcc";
}
```

Spring MVC with Thymeleaf

Step 19: spring boot Thymeleaf

```
<html xmlns="http://www.w3.org/1999/xhtml" xmlns:th="http://www.thymeleaf.org">
    <head>
        <meta charset="UTF-8">
    </head>
    <body>
        <table>
            <tr>
                <th>bookId</th>
                <th>isbn</th>
                <th>title</th>
                <th>authorName</th>
                <th>publisher</th>
                <th>price</th>
                <th>pubDate</th>
            </tr>
            <tr th:each="book : ${books}">
                <td th:text="${book.bookId}">Id</td>
                <td th:text="${book.isbn}">isbn</td>
                <td th:text="${book.title}">title</td>
                <td th:text="${book.authorName}">authorname</td>
                <td th:text="${book.publisher}">publisher</td>
                <td th:text="${book.price}">price</td>
                <td th:text="${book.pubDate}">pubDate</td>
            </tr>
        </table>
        <a href="#" th:href="@{/addbook}">Add book</a>
    </body>
</body>
</html>
```

```
<form action="#" th:action="@{/addbook}" th:object="${book}" method="POST">
    <table>

        <tr><td>ISBN</td>
            <td>
                <input type="text" th:field="*{isbn}" />
                <label th:if="#{fields.hasErrors('isbn')}" th:class="'error'">Enter isbn</label>
            </td>
        </tr>
        <tr><td>Gender</td>
            <td>
                <input type="radio" th:field="*{gender}" value="Male"/><label>Male</label>
                <input type="radio" th:field="*{gender}" value="Female"/><label>Female</label>
                <label th:if="#{fields.hasErrors('gender')}" th:class="'error'">Select Gender</label>
            </td>
        </tr>
        <tr><td>Married?</td>
            <td>
                <input type="checkbox" th:field="*{married}" />
            </td>
        </tr>
        <tr><td>Profile</td>
            <td>
                <select th:field="*{profile}">
                    <option th:each="profile : ${allProfiles}"
                           th:value="${profile}" th:text="${profile}">Profile</option>
                </select>
            </td>
        </tr>
        ...
        <tr><td colspan="2">
            <input type="submit" th:value="Submit"/>
            <input type="reset" th:value="Reset"/>
        </td>
    </tr>
    </table>
</form>
```

Blog and Comment application spring boot

how to map 1 to m:

```
@Entity  
@Table(name = "e_table")  
public class Employee {  
    @Id  
    @GeneratedValue(strategy = GenerationType.IDENTITY)  
    private int eid;  
    private String name;  
    private double salary;  
  
    @ManyToOne  
    private Department department;
```

```
@Entity  
@Table(name = "d_table")  
public class Department {  
    @Id  
    @GeneratedValue(strategy = GenerationType.IDENTITY)  
    private int did;  
    private String dname;  
  
    @OneToMany  
    private List<Employee> employees=new ArrayList<>();
```

reverse owner
mappedby

owner of relationship

```
@Query("SELECT new com.empapp.dto.EmpDeptResponse  
        (d.dname, e.name, e.salary) FROM Department d INNER JOIN d.employees e")  
  
public List<EmpDeptResponse>getEmpDeptInformation();
```

Step 21: Blog and Comment application spring

boot

```
@Entity
@Table(name="blog_table")
public class Blog {
    @Id @GeneratedValue(strategy=GenerationType.IDENTITY)
    private Long id;
    private String title;
    private String author;
    private String content;

    @OneToMany(mappedBy="blog", cascade=CascadeType.ALL)
    @JsonIgnore
    List<Comment> comments=new ArrayList<Comment>();

    public void addComment(Comment comment){
        comments.add(comment);
        comment.setBlog(this);
    }

    public void removeComment(Comment comment){
        comments.remove(comment);
        comment.setBlog(null);
    }
}
```

```
@Entity
@Table(name="comment_table")
public class Comment {
    @Id @GeneratedValue(strategy=GenerationType.IDENTITY)
    private Long id;
    private String comment;
    private LocalDateTime createdAt;
